Overview on the 32-bit Intel Architecture (IA Overview on Assembly Basic Instructions x86.64

# Assembly

- Low-Level Language
- Directly mapped with binary code
- Architecture-specific: x86, PowerPC, ARM, MIPS, ...

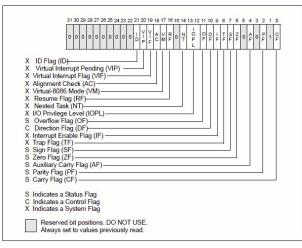

# IA-32: 32-bit internal registers

- General purpose: EAX, EBX, ECX, EDX
- Base Pointer: EBP
- Stack Pointer: ESP
- EDI, ESI source and dest index for special instructions (strcpy)
- ► EIP instruction pointer
  - Can't be read or set explicitly
  - Modified by jump and call/ret, read through the stack (saved EIP)

# Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions v86 64

### **EFLAGS**

# EFLAGS (cont.)

- It's another 32-bits register
- Only 8 bits out of 32 are of interest for us. The others are either for the kernel mode function or are of little interest for programmers
- These 8 bits are called flags. We consider them singularly.
   They are boolean (true/false)
- ► They represent overflow, direction, interrupt disable, sign, zero, auxiliary carry, parity and carry flags
- Since they represent information about the instruction last executed, they change at every execution step. They are VERY important for the control flow of the program

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

# A note on the terminology

```
byte 8 bits
word 2 bytes
dword double word, 4 bytes
qword quadruple word, 8 bytes
```

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86\_64

# Assembly: syntax

- ▶ There are two main syntaxes (different operand order!):
  - ► AT&T default on all UNIX programs (e.g., gdb, objdump)
  - ▶ Intel used by Windows programs (e.g., default on IDA Pro)

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86.64

# Syntax: AT&T vs. Intel

#### move the value 0 to EAX

AT&T Intel
mov \$0x0,%eax mov eax, 0h

#### Main differences

- In AT&T syntax the destination is the second operand, and vice-versa in Intel syntax
- ► In AT&T syntax registers are denoted with % and immediates (i.e., costants) with \$. In the Intel syntax these tokens are not used.

# Syntax: AT&T vs. Intel (pointer dereferencing)

move the value 0 to the address contained in EBX+4

AT&T Intel
mov \$0x0,0x4(%ebx) mov [ebx+4h],0h

#### Main differences

- ▶ Parentheses: round vs. square
- Offsets: out and before vs. inside with a '+' sign

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

### Basic instructions overview

- ► Every processor has a large instruction set (see Intel manual¹)
- A subset of the whole instruction set is usually processor dependent
- We will focus on the subset of instructions that is common among the processors
- We will use the Intel syntax as it is the same syntax used in IDApro by default
- Very good reference: http://ref.x86asm.net/geek32.html

<sup>1</sup>http://www.intel.com/content/www/us/en/processors/architectures-software-developer-manuals.html

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86.64

### Instructions

- ▶ Data Transfer: mov, push, pop, xchg, ...
- ► Integer Arithmetic: add, sub, mul, div, inc, dec, imul, idiv, ...
- Logical: and, or, not, xor, ...
- Control Flow: jmp, jne, call, ret, ...

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

# Basic Instructions: MOV

- MOV <u>destination</u>, <u>source</u> <u>source</u> can be an immediate, a register, a memory location <u>destination</u> can be either a register or a memory location NB: Every combination except memloc to memloc: It is invalid in every instruction!
- Move value from source to destination. There are tons of different versions, depending on the operands size (byte, word, dword), immediate to reg, immediate to memory, etc.
- Examples

MOV eax, ebx	MOV eax, FFFFFFFh	MOV ax, bx
MOV [eax],ecx	MOV [eax],[ecx] NO!!!	MOV al, FFh

## Basic Instructions: ADD

- ADD <u>destination</u>, <u>source</u>
   <u>source</u> can be an immediate, a register, a memory location
   <u>destination</u> can be either a register or a memory location
   NB: The destination has to be at least as large as the source.
- ▶ Semantic: destination = destination + source
- Examples

ADD esp, 44h	ADD eax, ebx	ADD al, dh
ADD edx, cx	ADD [eax],[ecx] NO!!!	ADD [eax],1h

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86.64

# Basic Instructions: SUB

- ► SUB <u>destination</u>, <u>source</u> <u>source</u> can be an immediate, a register, a memory location <u>destination</u> can be either a register or a memory location NB: The destination has to be at least as large as the source.
- ▶ Semantic: destination = destination source
- Examples

SUB esp, 33h	SUB eax, ebx	SUB al, dh
SUB edx, cx	SUB [eax],[ecx] NO!!!	SUB [eax],1h

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

## Basic Instructions: MUL

- MUL Operand **Operand** can be an immediate, a register, a memory location
- ▶ Multiplies **Operand** by the value of AL, AX, EAX register, depending on sizeof(Operand)

sizeof(Operand):	1 byte	2 bytes	4 bytes
Other operand	AL	AX	EAX
Most sign. part of result in:	AH	DX	EDX
Least sign. part of result in:	AL	AX	EAX

Examples

sizeof(Operand):	1 byte	2 bytes	4 bytes
Immediate	MUL 44h	MUL 4455h	MUL 44556677h
Register	MUL cl	MUL dx	MUL ebx

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

## Basic Instructions: DIV

- ▶ DIV <u>Operand</u>
   Operand can be an immediate, a register, a memory location
- ▶ Divides the value in the dividend register(s) by Operand

sizeof(Operand):	1 byte	2 bytes	4 bytes
Dividend	AX	DX:AX	EDX:EAX
Remainder	AH	DX	EDX
Quotient	AL	AX	EAX

Examples

sizeof(Operand):	1 byte	2 bytes	4 bytes
Register	DIV bl	DIV bx	DIV ebx
Immediate	DIV 66h	DIV 6677h	DIV 66778899h

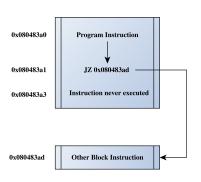

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86\_64

## Basic Instructions: CMP

- ► CMP **Operand\_1**, **Operand\_2**
- Operand\_1 minus Operand\_2 subtraction and sets the flags (ZF,CF,OF, etc.), it doesn't store the result
- Examples

CMP eax, ebx	CMP eax, 44BBCCDDh	CMP al, dh
CMP al, 44h	CMP ax,FFFFh	CMP [eax],4h

# Control-Flow Instructions: JMP

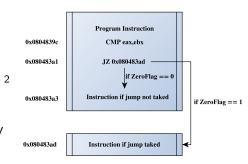

- ▶ JMP address or offset
- "Unconditional jump": sets the EIP to the address. We say that the execution "jumps to address" and it's unconditional because it always happens.
- Using an offset the current EIP is incremented (or decreased) by the constant expressed by the offset resulting in a relative jump.

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions ×86 64

# Control-Flow Instructions: JZ, JNZ, ...

- ► General: JX <u>address</u> or <u>offset</u> X  $\in$  {O, NO, S, NS, E, Z, NE...}
- These are called "conditional jumps"
- ► The execution will go to address if and only if the specific flag of the condition is verified.
- ► For example: JZ jumps if and only if ZF (zero flag) is 1
- Offset is used for relative position (as in JMP)

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions x86 64

# Basic Instructions: NOP

- ▶ NOP = **No Operation**. Just move to next instruction.
- ► The opcode is pretty famous and is 0x90
- Really useful in exploitation (we will see!)

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions ×86 64

# Interrupts: INT

- ► INT VALUE
- ▶ **VALUE** is the software interrupt number to generate (0-255)
- ► Famous values are 21h for call service under Windows and 80 for Linux
- Every OS has its set of interrupt numbers

Overview on the 32-bit Intel Architecture (IA) Overview on Assembly Basic Instructions ×86 64

# Syscalls: syscall and SYSENTER

Nowadays Syscalls are done with specific instructions.

- syscall is used for Linux 64-bit
- SYSENTER is used by Microsoft Windows

Overview on Assembly
Basic Instructions
v86 64

# How much is x86\_64 different from x86?

- ► The prefix of the registers is R instead of E so we have (RIP, RAX etc.)
- ► There are 8 new registers (**R8** to **R15**)
- ▶ each of them can be considered at 8, 16, 32, 64 bits (qword) with  $X \in \{8..15\}$  we have

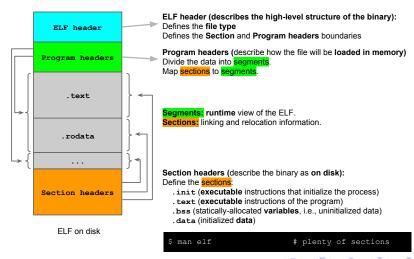

bits	8	16	32	64
reg	rXb	rXw	rXd	rX

for better syntax information look at http://www.x86-64.org/documentation/assembly.html

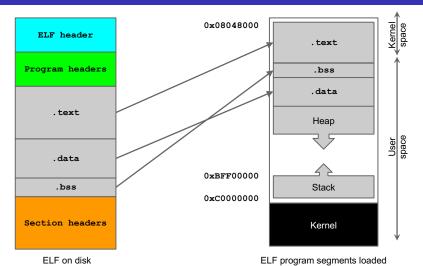

# Binary File Formats

- ▶ PE (Portable Executable): used by Microsoft binary executable.
- ► ELF: common binary format for Unix, Linux, FreeBSD and others
- ► We are interested in how each executable is mapped into memory, rather than how it is organized on disk.

# **ELF Binaries**

# Process Layout in Linux

# How an executable is mapped to memory in Linux (ELF)

Executable	Description
.bss	This section holds uninitialized data that contributes to the program's memory image.
	By definition, the system initializes the data with zeros when the program begins to run.
.comment	This section holds version control information.
.data/.data1	These sections hold initialized data that contribute to
	the program's memory image
.debug	This section holds information symbolic debugging.
.text	This section holds the "text," or executable instructions, of a program.
.init	This section holds executable instructions that contribute to the process initialization code.
	That is, when a program starts to run, the system arranges to execute the code in this
	section before calling the main program entry point (called main for C programs).
.got	This section holds the global offset table.

# How an executable is mapped to memory in Windows (PE)

Executable	Description
.text	Contains the executable code
.rdata	Holds read-only data that is globally accessible within
	the program
.data	Stores global data accessed throughout the program
.idata	stores the import function information;
.edata	stores the export function information;
.pdata	Present only in 64-bit executables and stores
	execption-handling information
.rsrc	Stores resources needed by the executable
.reloc	Contains information for relocation of library files

# A more realistic view of an elf in memory

Low addresses (0x80000000)

Shared libraries
.text
.bss
heap (grows ↓)
• • •
stack (grows ↑)
env
argc

High addresses (0xbfffffff)

31 / 52

### Instructions: stack

#### push

- Example: PUSH immediate or PUSH register
- Pushes the immediate or register value at the top of the stack and decrements the ESP of sizeof(immediate or register)

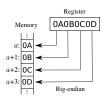

#### pop

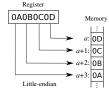

- Example: POP destination
- Pops the word off of the top of the stack and moves it at destination, then it increases the ESP of sizeof(data popped).

### **Endianness**

The **endianness** is a convention that specifies in which order the bytes of a data word are lined up sequentially in memory.

**Big-endian** systems are systems in which the *most significant byte* of the word is stored in the *smallest address* given.

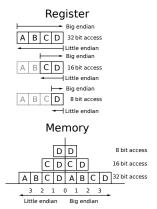

**Little-endian** systems are those in which the *least significant* byte is stored in the *smallest address*. [A-32 is "little endian").

### Endianness cont.

The **endianness** is a convention that specifies in which order the bytes of a data word are lined up sequentially in memory.

### **Functions**

#### **Function**

piece of code that receives data from the caller, execute code and returns some value

### Calling Convention

- How a function receives parameters and returns the value and how it administers the stack
- ► The high-level language, the compiler, the OS, and the target architecture all together "implement" and "agree upon" a certain calling convention (it's part of the ABI, the Application Binary Interface).

#### **Functions**

#### call func

- Push to the stack the address of the next instruction (return address): PUSH EIP
- Move the address of the first instruction of func into EIP: .JMP func

#### ret

Returns to the previous function (i.e., caller), restoring the return address saved by call (POP EIP;)

#### leave

Restore the caller's stack pointer (mov ESP EBP; pop EBP;)

# The C Calling Convention

- ► It's the default calling convention used by most C compilers for the x86 architecture
- When a compiler doesn't use this convention we can force it using the modifier <u>cdecl</u>
- ▶ It specifies that the **caller places** parameters on the stack in the right to left order and that the **caller removes** the parameters from the stack after the called function completes

# The C Calling Convention example

```
void demo_cdecl(int a, int b, int c, int z);
//...
demo_cdecl(1, 2, 3, 4); //calling
```

```
; ...
push 4 ; push last parameter value
push 3 ; push third parameter value
push 2 ; ...
push 1
call demo_cdecl ; call the subroutine
```

# A Closer Look at the cdecl Calling Convention

```
void function (int a, int b) {
  int array [5];
}
int main (int argc, char** argv) {
  function(1, 2);
  printf("This is where the ret
      address points");
}
```

Low memory addresses (top of the stack)

```
array[0]
Saved EBP
return address
1
2
```

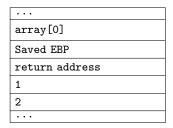

High memory addresses (bottom of the stack)

### Assembler-level View of the Same Example

```
public main
main proc near
push ebp
mov ebp, esp; create stack
and esp.OFFFFFFFOh
sub esp.10h : make room for vars
mov dword ptr[esp+4],2; push 2
mov dwrod ptr[esp],1 ; push 1
call function
mov dword ptr [esp], offset format; "This is..."
call _printf
leave
ret
main endp
public function
function proc near
push ebp
mov ebp.esp : create stack
sub esp,20h; make room for array
leave
retn 8 : remove 2 dwords
function endp
```

Low memory addresses (top of the stack)

High memory addresses (bottom of the stack)

# The Standard Calling Convention

- ► This is Miscrosoft's calling convention standard
- When a compiler doesn't use this convention we can force it using the modifier \_stdcall
- ► The parameters are passed using the stack as in \_cdecl, but in \_stdcall the called function is responsible for clearing the function parameters from the stack before returning. To do this, the function needs to know the right number of parameter passed. Can be used only with functions having a fixed number of parameters (e.g., no printf).

```
void _stdcall demo_stdcall(int a, int b, int c);
demo_stdcall(1, 2, 3);
```

ret 12; return and clear 12 bytes from the stack

#### fastcall Convention for x86

- Variation of the standard calling convention
- passes up to 2 parameters via registers (faster than stack).
- ► The Microsoft Visual C/ C++ and GNU GCC/g++ compilers recognize the fastcall modifier in function declaration.
- Example: the 1st and 2nd parameters are passed via ECX and EDX, the remainder parameters pushed on the stack in right to left order. The called function must cleanup the stack when returning.

```
; demo_fastcall(1, 2, 3, 4);
push 4 ; push 4th parameter
push 3 ; push 3rd parameter
mov edx, 2 ; move 2nd parameter in EDX
mov ecx, 1 ; move 1st parameter in ECX
call demo_fastcall
```

# Linux x86-64 calling convention (System V ABI)

- ► Parameters passed **in registers**: rdi, rsi, rdx, rcx, r8, r9, subsequent ones on the stack (reverse order)
- ► Callee-saved registers: rbx, rsp, rbp, r12, r13, r14, and r15
- Caller-saved registers (scratch): rax, rdi, rsi, rdx, rcx, r8, r9, r10, r11
- Return value: rax (if 128-bit: rdx)

# Linux x86-64 calling convention: a closer look

```
main:
 push rbp
 mov rbp, rsp
 sub rsp, 16
 mov DWORD PTR [rbp-4], edi
 mov QWORD PTR [rbp-16], rsi
 mov esi, 2 ; Second parameter
 mov edi, 1 ; First parameter
 call function
 mov esi, eax ; Return value -> first param
 mov edi, OFFSET FLAT:.LCO; "The return ...
 mov eax. 0
 call printf
 leave
 ret
function:
 push rbp
 mov rbp, rsp
 mov DWORD PTR [rbp-4], edi
 mov DWORD PTR [rbp-8], esi
 mov edx, DWORD PTR [rbp-4]
 mov eax, DWORD PTR [rbp-8]
 add eax, edx
 pop rbp
 ret.
```

Low memory addresses (top of the stack)

```
2 (loc.)
1 (loc.)
Saved RBP
return address
```

# Objdump

- man objdump objdump displays information about one or more object files.
- -x all-headers
- -d disassemble
- -M intel intel syntax (default is att)

# Our friend gdb

#### What is GDB?

GDB is GNU Project's Debugger: allows to follow, step by step, at assembler-level granularity, a running program, or what a program was doing right before it crashed.<sup>3</sup>

<sup>&</sup>lt;sup>3</sup>http://www.gnu.org/software/gdb/

# Start, break and navigate the execution with gdb

- Suppose you have an executable binary and want run it
  - gdb /path/to/executable loads the binary in gdb
- Now you decide to start the program with two parameters
  - run 1 "abc" passes 1 via argv[1] and "abc" as argv[2]
  - run 'printf "AAAAAAAAAAA" (with the back ticks) we're passing the output of the print (very useful when you need to pass non printable characters such as raw bytes)
- Suppose you want to stop the execution at the address of a certain instruction
  - break \*0xDEADBEAF places a break point at that address
  - break \*main+1 with debugging symbols this can be less painful
  - catch syscall block the execution when a syscall happens

# Start, break and navigate the execution with gdb

- Now the execution stops at our break point. Here we can do several things
- Examples:
  - ni allows to procede instruction per instruction
  - next 4 moves 4 lines ahead (if you have the line-numbers information in the binary)
  - ▶ si step into function
  - finish run until the end of current function
  - continue runs until the next break point (if any)
- ▶ To see info about the execution state:
  - ▶ **info registers** to inspect the content of the registers
  - info frame to see the values of the stack frame related to the function where we are in
  - info file print the information about the sections of the binary

# Navigate the stack

- Suppose we're stopped somewhere in the code and want to inspect the stack
- ▶ Some useful view of the stack is achievable with:
  - $ilde{x}/100wx$  \$esp prints 100 words of memory from the address found in the ESP to ESP+100 (x = hexadecimal formatting)
  - x/10wo \$ebp-100 prints 10 words of memory from EBP-100 to EBP-100+10 (o = octal formatting)
  - x/s \$eax prints the elements pointed by EAX (s = string formatting)
- Do you have debug symbols? (i.e., gcc -ggdb)
  - print args prints info about the main parameters
  - **print a** prints the content of variable 'a'
  - print \*b prints the value pointed by 'b'

# Our friend gdb

▶ The ' $\sim$ /.gdbinit' file

Gdb is a command line tool and it supports the configuration script as almost all the \*nix software.

Some options that you may want to tune are:

- set history save on
   To have the lastest commands always available also when we re-open gdb
- set follow-fork-mode child Allows you, if the process spawns children, to follow them and not only wait their end.
- set disassembly-flavor [intel | att] This option sets in which predefined syntax your disassembled will be showed up. The default one is at&t
- Highly recommended to put this https://github.com/gdbinit/Gdbinit file in ~/.gdbinit

# Layout in gdb

- You're not a big fun of the gdb command line?
- Give a simple text-based interface to it
  - layout asm turn the interface to the assembly view always visible during debugging
  - layout src if your binary has the dubugging symbols you will have your c source view visible
  - layout reg add to the interface the register status view. It could be used in combination with one of the view described above
  - ▶ gdb -tui ./mybin runs gdb directly in this Text User Interface
- ▶ Use CTRL+X A to go back to standard interface.

#### End

That's all folks!
Time for (more) questions!
